The background of the slide is a microscopic view of red blood cells, which are biconcave discs. They are rendered in a light blue/cyan color with a slight 3D effect, showing their characteristic shape and some internal texture. The cells are scattered across the frame, with some in sharp focus and others blurred in the background.

Why Old Blood is Bad

...tales from the electronic perfusion
record

Plan of Attack

- Why blood has the potential to be good
- Why old blood can be bad
- What does the electronic perfusion record tell us?
- Would washing donor RBC's help?

The background of the slide features a light pinkish-red color with several semi-transparent, stylized red blood cells scattered across it. The cells are depicted as biconcave discs, with some showing a darker center to represent the indentation. They are arranged in a way that creates a sense of depth and movement, as if they are floating or circulating.

Allogeneic Red Blood Cells

Why Blood Can Be Good

- **Oxygen Carrying Capacity**

$$\text{CaO}_2 = (1.34 \times \text{Hgb} \times \text{SaO}_2) + \underline{(0.0031 \times \text{PaO}_2)}$$

100%

- Administration of donor RBC's can increase the CaO_2 , thereby increasing oxygenation

Why Blood Can Be Good

- **2,3-Diphosphoglycerate (2,3-DPG)**

Lowers affinity
of Hemoglobin
molecule for
oxygen →
oxygen released
to tissues

Why Blood Can Be Good

- **Adenosine Triphosphate (ATP)**
 - Intracellular energy source
 - Intracellular signaling molecule
 - RBC's release ATP in response to hypoxia, pH, and mechanical stress
 - Increase production of nitric oxide (NO)
 - Vasodilator under hypoxic conditions

Why Blood Can Be Good

- **Red Blood Cell shape**
 - Round, elastic, bi-concave discs
 - Large surface area for O_2 diffusion
 - Flexibility allows RBC's to pass through capillaries as narrow as $3\mu\text{m}$
 - Rouleaux formation

The background of the slide features a field of red blood cells, depicted as biconcave discs, scattered across a light blue and purple gradient. The cells are rendered with soft shading to give them a three-dimensional appearance.

The Storage Lesion

(aka Why Old Blood is Bad)

Why Old Blood is Bad

- **Loss of 2,3 DPG**
 - Decreases quickly in first 2 weeks of storage to almost undetectable levels
 - Increased O_2 affinity
 - Levels appear to recover post-transfusion
 - Up to 72 hours
 - Studies suggest minimal physiological impact

Why Old Blood is Bad

- **Decreased Intracellular ATP**
 - 40% reduction @ 35-42 days
 - Associated with the reduced oxygen-delivery capacity
 - Can induce RBC shape changes
 - Levels recover in-vivo

ATP ($\mu\text{mol/g Hb}$)

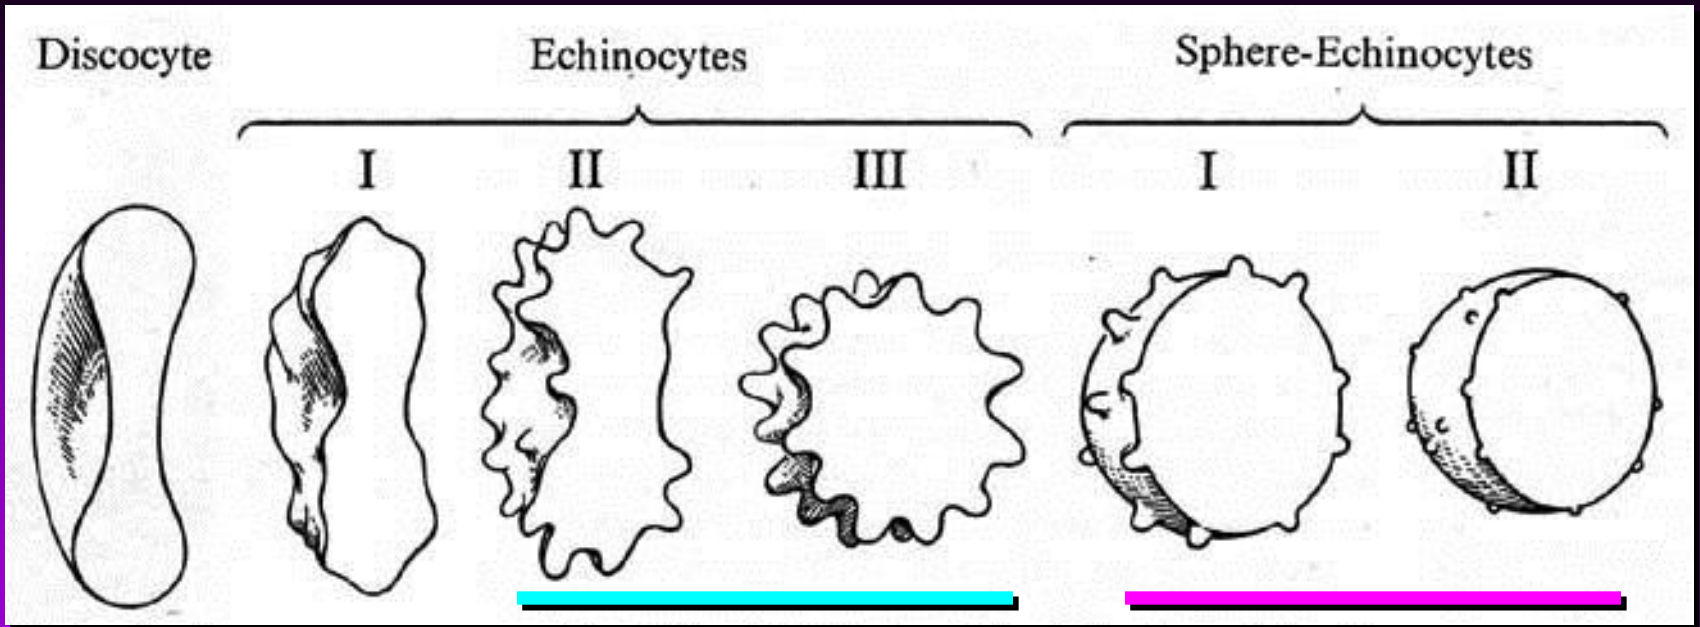

Source: Salzer U, et al. Vesicles generated during storage of red cells are rich in the lipid raft marker stomatin. *Transfusion* 2008; 48: 451-62.

Why Old Blood is Bad

- **Morphological changes**
 - Biconcave discs
 - Echinocytes with protrusions
 - Spherocytes
 - Formation of microvesicles
 - Loss of membrane phospholipids

Why Old Blood is Bad

- **Morphological changes**
 - Decreased membrane deformability
 - Increased aggregability
 - Increased adhesion to endothelium
 - Minimizes ability to flow through microcirculation
 - Influences RBC transport of O_2 to tissues
 - Increased osmotic fragility
 - Hemolysis

Hemolysis (%)

Why Old Blood is Bad

- **Other Changes**

- ↑ Potassium
- ↓ Sodium
- ↓ pH
- ↑ Lactate
- ↓ Glucose

Glucose (mmol/L)

The background consists of numerous light blue, rounded rectangular shapes scattered across a slightly darker blue gradient. These shapes resemble soft, pill-like objects or perhaps stylized letters, creating a textured, three-dimensional effect.

The Word on the Street

- 2872 patients who received 8802 units of blood \leq 14 days old

- 3130 patients who received 10,782 units of blood $>$ 14 days old

- Blood older than 2 weeks was associated with a significantly increased risk of postoperative complications as well as reduced short-term and long-term survival

duration of storage on outcomes. Survival was estimated by the Kaplan–Meier method and Blackstone’s decomposition method.

- Four groups based on PRBC age:
 - <10 days
 - 10-14 days
 - 15-19 days
 - >19 days

Transfusion of RBCs increased cerebral oxygenation except in those transfused with RBCs stored > 19 days.

Measurements and Main Results: PtiO₂, cerebral perfusion pressure, mean arterial pressure, intracranial pressure, peripheral oxygen saturation, CO₂ pressure at the end of expiration, and intracerebral

KEY WORDS: brain hypoxia; cerebral oxygenation; erythrocytes; neurotrauma; brain tissue oxygen pressure; red blood cells; severe brain injury; transfusion

Does the storage time of transfused red blood cells influence

- Two groups: blood \leq 5 days old, blood \geq 20 days old
- Measured gastric pH as index of gastric oxygenation status
- No change in oxygenation with *any* transfusion
- Blood transfusion worthwhile?

days was 2 days (first and third quartile, 2, 2.25; range, 2–3); red cells stored \geq 20 days had a mean age of 28 days (first and third quartile, 27, 31; range, 22–32). Hemoglobin concentration in-

Association between duration of storage of transfused red blood cells and morbidity and mortality in adult patients: myth or reality?

Christophe Lelubre, Michael Piagnerelli, and Jean-Louis Vincent

BACKGROUND: The duration of red blood cell (RBC) storage before transfusion may alter RBC function and, therefore, influence the incidence of complications.

STUDY DESIGN AND METHODS: With a computerized literature search from 1983 to 2008, 27 studies reporting the relationship between age of transfused RBCs and physiologic variables or incidence of complications in adult patients were identified.

RESULTS: Three studies (one abstract only, two foreign language) were excluded. The 24 remaining studies were grouped according to the patient population: cardiac surgery (eight studies), colorectal surgery (three), intensive care unit (ICU; seven), and trauma (six). The studies were too heterogeneous to allow a formal meta-analysis. Twenty-one of the 24 studies were single-center, and 12 were retrospective. The number of patients was highly variable, ranging from 15 to 6002. In cardiac surgery, two studies reported an increased risk of mortality but had statistical limitations. In colorectal surgery, two studies that addressed the effect on postoperative infections in the same database but with different designs yielded conflicting results. In general ICU patients, two retrospective studies reported a significant correlation between length of RBC storage and microcirculatory alterations or mortality, but the results were not confirmed in subsequent prospective, double-blinded studies. In trauma, five studies reported a correlation between RBC age and development of infection, multiple organ dysfunction, or mortality.

CONCLUSIONS: From the currently available published data, it is difficult to determine whether there is a relationship between the age of transfused RBCs and outcome in adult patients, except possibly in trauma patients receiving massive transfusion.

Red blood cell (RBC) transfusion can be associated with adverse events, including the transmission of infective agents (e.g., human immunodeficiency virus, hepatitis B and C viruses, and bacteria), acute and delayed hemolytic transfusion reactions, transfusion-related acute lung injury, transfusion-associated graft-versus-host disease, and so-called transfusion-related immunomodulation. Numerous studies have indicated that RBC transfusions may be associated with an increased risk of morbidity (postoperative infection,¹⁻³ longer duration of hospital or intensive care unit [ICU] stay,^{4,5} duration of mechanical ventilation,⁴ multiple organ failure [MOF]⁶) and/or mortality.^{5,7}

RBC storage lesion, defined as biochemical and biomechanical changes in the RBC and the storage media during *ex vivo* preservation,^{8,9} may exacerbate this transfusion-associated morbidity and mortality.¹⁰ Biochemical changes occurring during storage include an enhanced susceptibility to oxidative damage,^{11,12} and a decrease in adenosine triphosphate (ATP), 2,3-diphosphoglycerate,¹³ and membrane sialic acid.¹⁴ Changes to the storage medium also occur, with a progressive decrease in pH, an increase in plasma potassium, release of free hemoglobin (Hb) from lysed RBCs¹⁵ (binding

ABBREVIATIONS: CABG = coronary artery bypass grafting; ICU = intensive care unit; IQR = interquartile range; LOS = length of stay; MOF = multiple organ failure; pH = gastric mucosal pH; P_{ti}O₂ = cerebral tissue oxygenation; SAGM = saline-adenine-glucose-mannitol.

TRANSFUSION **:**:**

“From the currently available published data, it is difficult to determine whether there is a relationship between the age of transfused RBC’s and outcome in adult patients, except possibly in trauma patients receiving massive transfusion.”

The background of the slide features a dense field of red blood cells, depicted as biconcave discs, in various shades of red and pink. The cells are scattered across the frame, creating a textured, biological appearance.

Utilization of the EPR

- Use of the third timer on the Sorin S3 pump allows us to track transfusion time
- Three time points:
 - Pre-transfusion
 - Transfusion
 - Post-transfusion
- Data collected every 20 seconds

Utilization of the EPR

- At the end of each case, data is wirelessly exported to a desktop computer
- That data can then be exported from the DMS program as an Excel file for evaluation

- Data separated into worksheets for 18 different variables
- Pre-, during, and post-transfusion

Variables

- Cardiac Index
- MAP
- Temperature
- Sweep Rate
- FiO_2
- Hemoglobin
- Invos (Right)
- Invos (Left)
- SVR
- pH
- SvO_2
- SaO_2
- $PaCO_2$
- PaO_2
- HCO_3
- Oxygen Consumption
- Oxygen Delivery
- Oxygen Extraction Ratio

Variables

- Cardiac Index
- MAP
- Temperature
- Sweep Rate
- FiO_2
- Hemoglobin
- Invos (Right)
- Invos (Left)
- SVR
- pH
- SvO_2
- SaO_2
- PaCO_2
- PaO_2
- HCO_3
- Oxygen Consumption
- Oxygen Delivery
- **Oxygen Extraction Ratio**

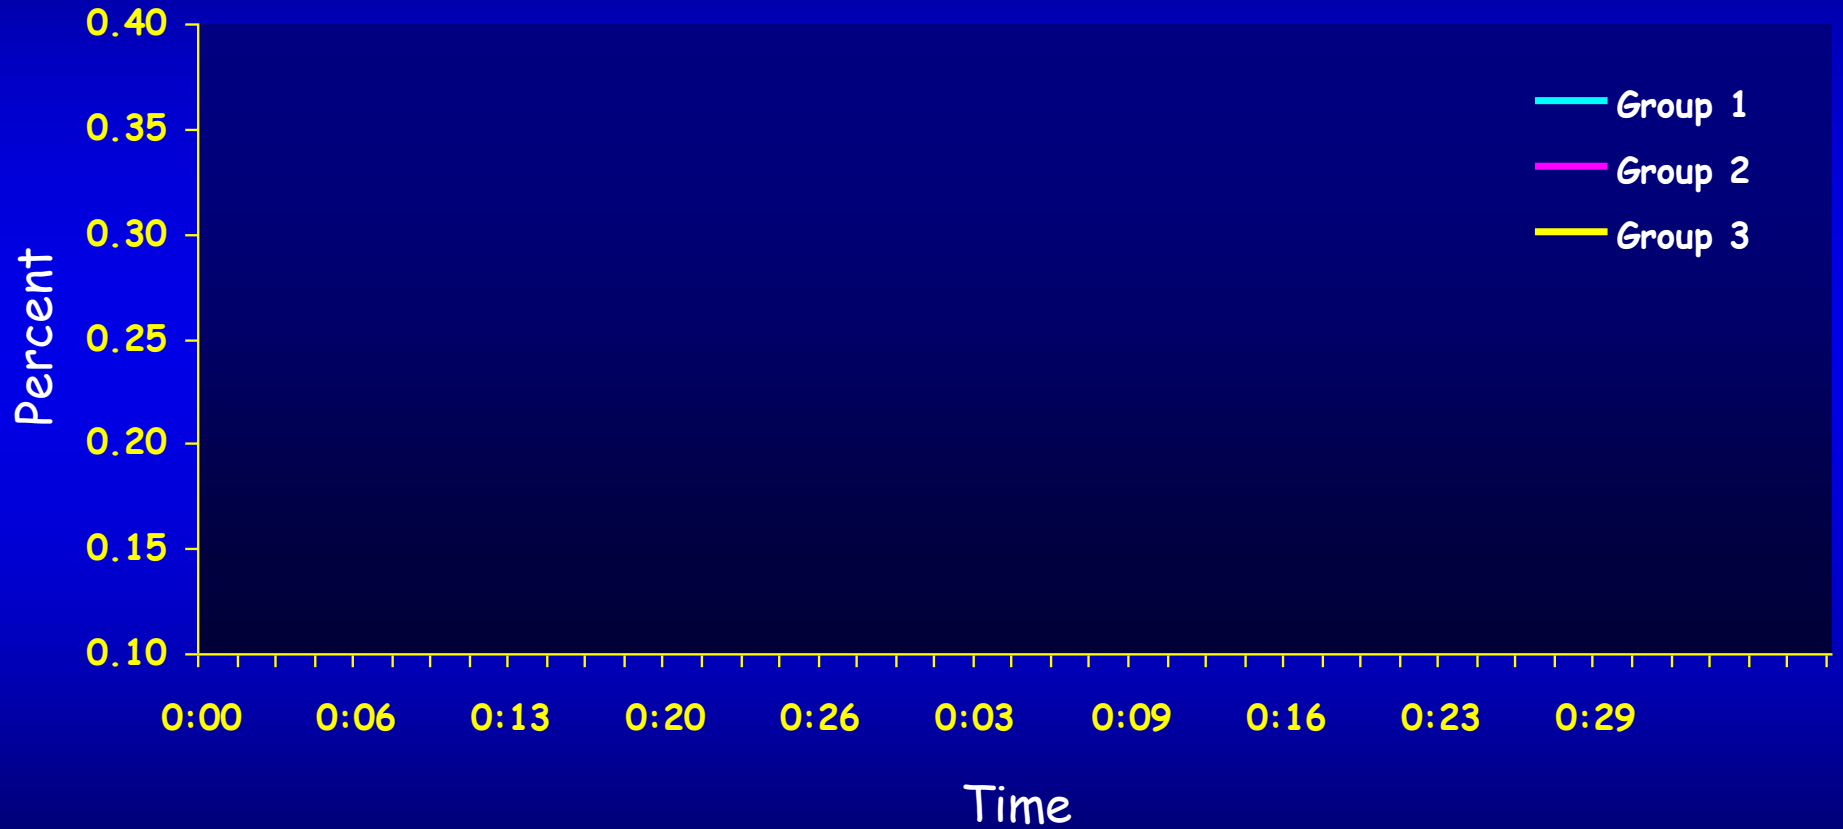

Oxygen Extraction Ratio (O_2ER)

- Index of global oxygenation
- Measure of the fractional tissue uptake of oxygen from the blood at the microcirculation level
- $O_2ER = VO_2/DO_2$
- Normal value $\leq 30\%$

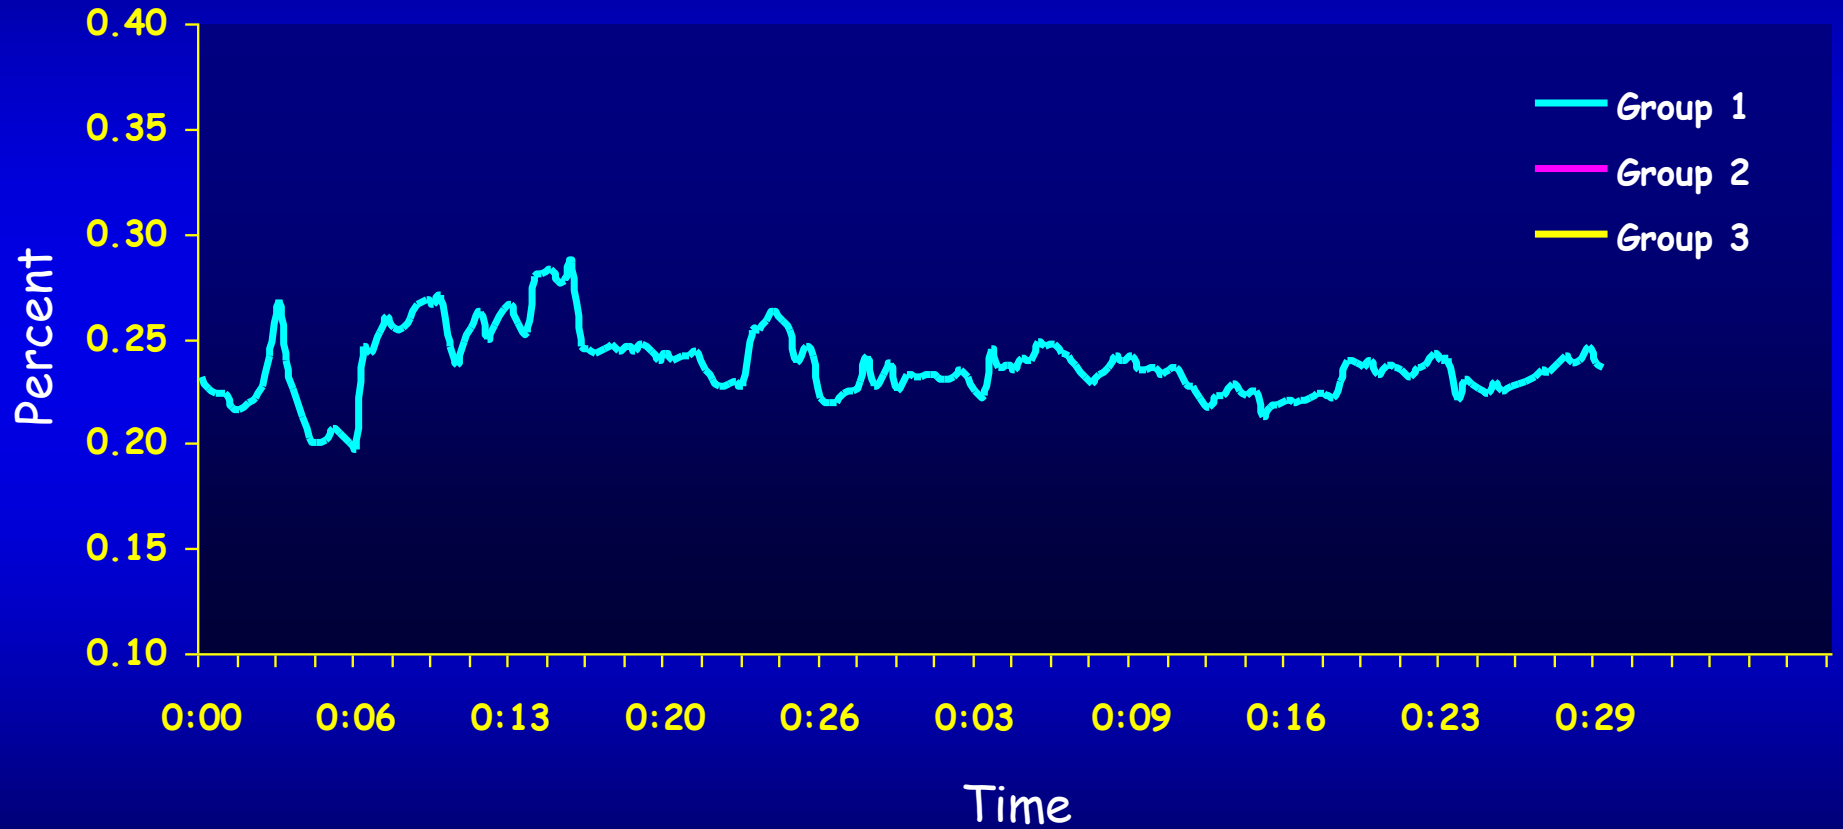

Data Analysis

- Transfusion data separated into 3 groups based on blood age
 - **Group 1: 0 - 15 days old**
 - **Group 2: 16 - 28 days old**
 - **Group 3: 29 - 42 days old**
- Multiple, concurrent transfusions of same age counted as same event
- Multiple, concurrent transfusions of different ages counted as same event but categorized by oldest unit

Oxygen Extraction Ratio

Oxygen Extraction Ratio

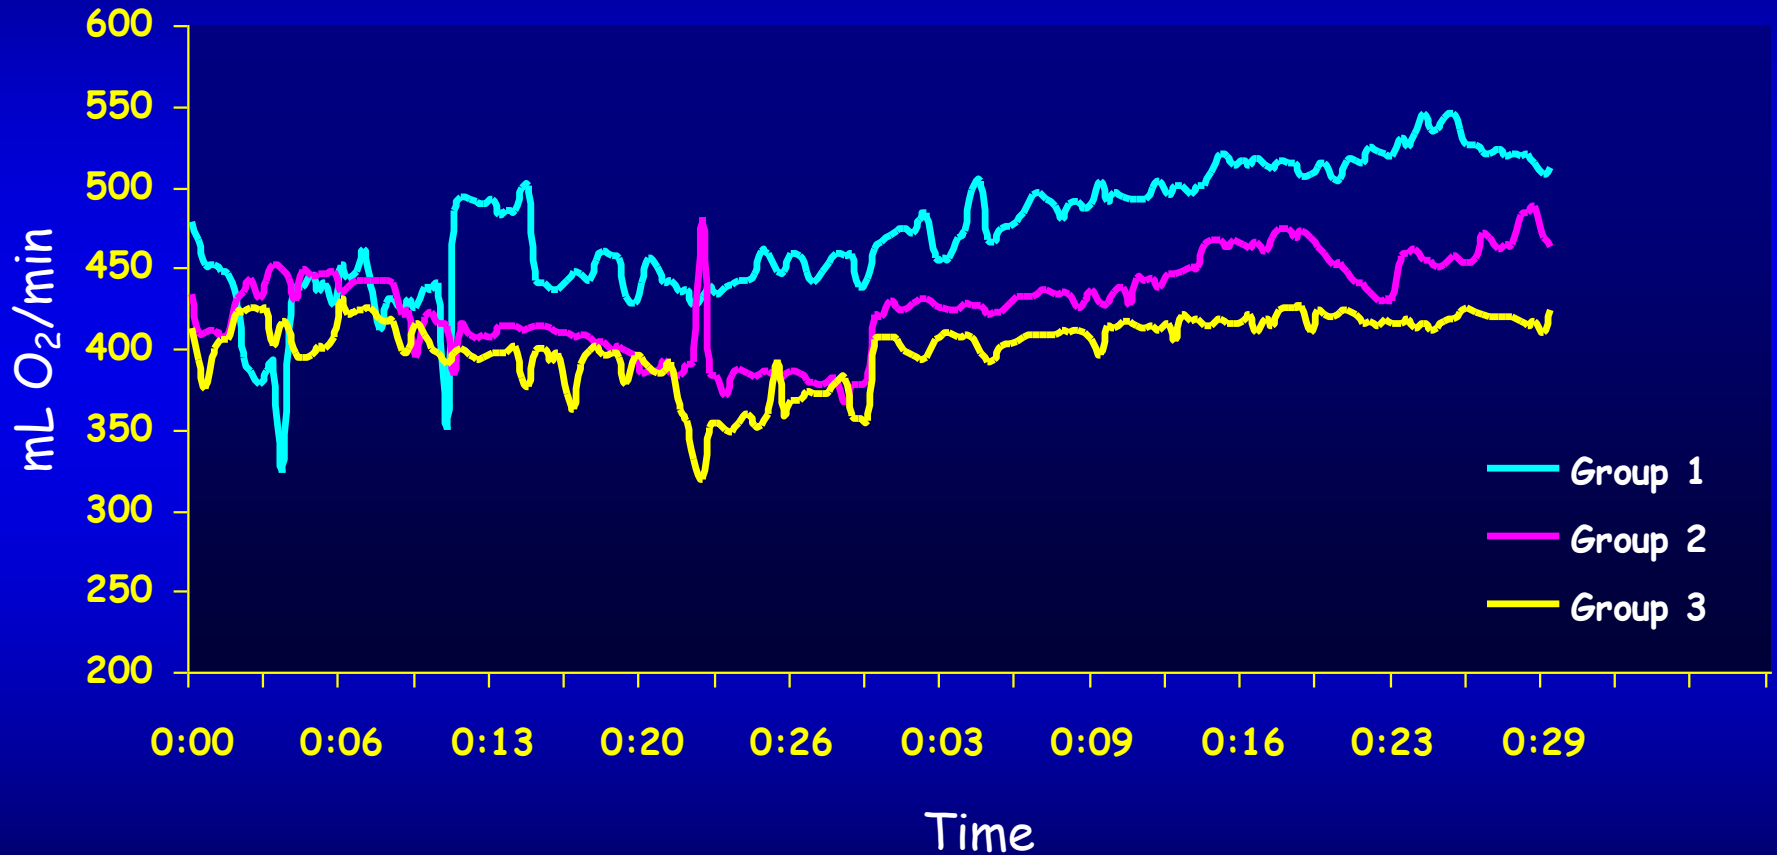

Oxygen Extraction Ratio

Oxygen Extraction Ratio

Oxygen Delivery (DO_2)

$$DO_2 = Q \times [(1.34 \times Hgb \times SaO_2)]$$

Oxygen Delivery (DO_2)

$$DO_2 = Q \times [(1.34 \times Hgb \times SaO_2)]$$

Cardiac Index

$$DO_2 = Q \times [(1.34 \times Hgb \times SaO_2)]$$

Cardiac Index

$$DO_2 = Q \times [(1.34 \times \text{Hgb} \times \text{SaO}_2)]$$

Hemoglobin

$$DO_2 = Q \times [(1.34 \times \text{Hgb} \times SaO_2)]$$

PaO₂

Oxygen Consumption (VO_2)

Venous Oxygen Saturation (SvO_2)

Mean Arterial Pressure

Points of Interest

- Noticeable and consistent differences between the three groups of blood
- Oxygen extraction least in oldest blood
 - Venous saturation greatest in oldest blood
 - Strongly suggests decreased ability of old blood to release oxygen to microcirculation

Limitations

- Observational study
- Cannot isolate storage lesion variables to determine cause and effect
- Limited power of certain variables due to small sample size

Somanetics

Future Direction

- Continue to collect and analyze data
- Data analysis to show statistical significance
- Compute changes in oxygenation variables
- Correlate data to outcomes
- Compare washed RBC's to unwashed RBC's
- Create a multi-institutional data set among other DMS users

**To Wash or Not
To Wash**

A comparative study of reducing the extracellular potassium concentration in red blood cells by washing and by reduction of additive solution

248 TRANSFUSION Volume 47, February 2007

Ila Bansal, Beverly W. Calhoun, Cherilyn Joseph, Mohammad Pothiaiwala, and Beverly W. Baron

pRBCs 3-21 days old

“Washing pRBCs results in very low levels of K+.”

0.0005). Washing, however, was significantly better than AS reduction in reducing K⁺ in stored pRBCs ($p < 0.05$).

CONCLUSIONS: Washing pRBCs results in very low levels of K⁺. AS reduction also significantly reduces K⁺ levels. Selection of the method of K⁺ reduction will depend on the stringency of K⁺ reduction needed, the time constraints, and the availability of facilities and staff for washing.

to determine whether a simpler procedure, AS reduction, results in reduction of K⁺ in pRBCs comparable to that achieved by washing, we compared the K⁺ levels in blood units subjected to both methods.

ABBREVIATION: pRBCs = packed red blood cell units.

Washing of stored red blood cells by an autotransfusion device before transfusion

- Free lactate and potassium significantly reduced
- RBC osmotic resistance improved
- RBC aggregation capacity reduced
- Deformability and Free Hgb unchanged

Received: 13 April 2006,
revised 30 August 2006,
accepted 8 September 2006,
published online 12 December 2006

Conclusion Washing stored blood before transfusion may be of benefit, because the waste products are effectively removed from the stored RBC.

Key words: aggregation, autotransfusion device, deformability, RBCs, transfusion, washing.

The Effect of Preprocessing Stored Red Blood Cells on Neonates Undergoing Corrective Cardiac Surgery

Mean age of RBC's ~ 15 days

Table 3. The Differences of Blood Variables in Unprocessed PRBCs in C Group and Processed PRBCs in P Group

	Hematocrit (%)	Lactate (mmol/L)	Blood Glucose (mmol/L)	Potassium (mmol/L)	Base Excess (mmol/L)
C group	42.4 ± 3.5	10.5 ± 2.1	17.2 ± 2.1	15.2 ± 3.5	-28.4 ± 4.2
P group	65.7 ± 8.1*	3.2 ± 0.8*	9.3 ± 1.7*	7.3 ± 2.8*	-27.8 ± 3.9

Comparing with C group.

* $p < 0.01$.

blood glucose, $[K^+]$, and lactate

CPB ($p < 0.01$), and lower than that of C group at the end of CPB ($p < 0.05$). The total priming of PRBCs in P group was significantly less than that in C group ($p < 0.01$). Perioperative processing with CATS provided a high-quality RBC concentration, decreased the total priming of PRBCs, providing increased high-quality blood salvage during neonatal CPB procedure. *ASAIO Journal* 2007; 53:680-683.

The study was approved by Fuwai Hospital, Beijing, China. Before surgery, parents of every patient participating in this investigation gave informed written consent. From May 2005 to December 2006, 16 neonates with congenital heart disease undergoing cardiac surgery with CPB were randomly assigned to two groups: P group ($n = 8$) received the processed PRBC before priming with CATS (Fresenius, Bad Homburg, Germany); C group ($n = 8$) received unprocessed PRBC for prim-

To Wash or Not To Wash?

- Research has demonstrated:
 - Decreased potassium load
 - Decreased lactate load
 - Increased hematocrit
- Within the Geisinger Health System all donor RBC's are washed prior to transfusion in cases utilizing ATX
 - Exception: emergent need for RBC's
- Negatives to this practice?

Take Home Messages

- After 15 days of storage:
 - 2,3 DPG, ATP, and RBC survivability decreases
- Clinical significance is inconclusive based on current studies
- The Electronic Perfusion Record may assist in elucidating these differences
- The age of donor RBC's has an effect on oxygenation variables
